

Chicago Flu Update

Rahm Emanuel, Mayor

January 18, 2013

Chicago Department of Pub Bechara Choucair, MD, Commissione

Influenza Activity

Influenza activity continues to decrease. However, data from all surveillance systems presented in this report suggest ongoing transmission of influenza virus in Chicago. Vaccination is the best way to protect against influenza infection and all Chicagoans aged six months and older are encouraged to get vaccinated. People who have not already gotten a flu vaccine this season should do so now. Healthcare providers and retail pharmacies continue to have vaccine available. For those without healthcare providers or insurance, a complete list of CDPH Immunization clinics¹ is available on the City website and by calling 311.

Are severe cases of influenza occurring?

associated deaths, influenza-associated ICU hospitalizations and outbreaks of influenza-like illness in a congregate setting should all be reported to CDPH via INEDSS². For the week of January 6-12, 2013 (week 2), 9 influenzaassociated ICU hospitalizations were reported; all were positive for influenza A (4 H3N2 and 5 were not subtyped). This represents a 71% decrease from the previous week.

Since September 30, 2012, 133 influenza-associated ICU hospitalizations have been reported, over two times the total number of cases reported for all of last season (Figure 1). Among the total ICU hospitalizations reported, 131 were positive for influenza A (69 H3N2, 6 H1N1, and 62 not subtyped) and 2 were positive for influenza B. Eightyone (61%) were female, 55 (41%) were African-American, and 98 (74%) were 50 years of age or older (median age of 64 years with a range between 6 months-96 years). Fiftyfive (42%) had lung disease, 47 (36%) had cardiac disease and 32 (24%) required ventilator support. Eight adult deaths were reported. All were 50 years of age or older, 63% were female, half had lung disease and a quarter were immunocompromised.

How much influenza-like illness is occurring?

CDPH receives data from over 50 surveillance sites across Chicago, which report the total number of patient visits per week, and of those visits, the number with influenza-like illness (ILI) (i.e., fever of 100°F or greater, with cough or sore throat). All hospitals in Chicago are required to report on a weekly basis the total number of emergency department visits, and of those visits, the number with ILI. For the week of January 6-12, 2013, with 15 hospitals reporting, 4.7% of emergency department visits were due to ILI. This is the second consecutive week that a decrease has been noted, however levels are almost twice where they were during the same week last season (Figure 2).

Figure 1. Number of influenza-associated intensive care unit Suspected novel and variant influenza, pediatric influenza- hospitalizations reported for Chicago residents, for current season (2012-2013) and previous season (2011-2012), October-May.

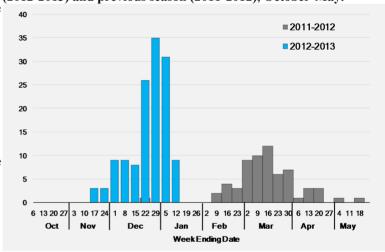

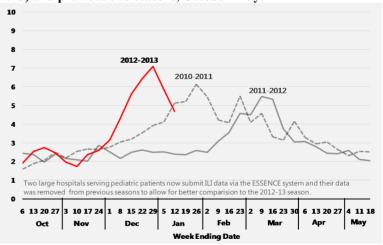

Figure 2. Percent of emergency department visits attributed to influenza-like illness based on manual reporting as determined by individual hospitals, Chicago, by week, for current season (2012-2013) and previous two seasons, October-May.

ESSENCE is an electronic syndromic surveillance system that utilizes emergency department chief complaint data submitted daily by participating Chicago hospitals. ILI activity is determined by an algorithm solely based on the patient's chief complaint and does not take into account the entire medical record, as the ILI activity reported in Figure 1 does. Currently, 9 Chicago hospitals submit data to ESSENCE. Figure 3 shows the percent of the total emergency department visits due to ILI for pediatric patients (3.9%) and adult patients (3.6%) for the week of January 6-12, 2013 plus the ILI activity by age group for the previous season. During the past four weeks, there has been less than a percentage point difference between pediatric and adult ILI levels.

Several outpatient clinics and two large outpatient clinic net- Figure 3. Percent of emergency department visits attributed to Illness Surveillance Network (ILINet) by reporting on the number of patients with ILI seen weekly. From January 6-12, 2013, with 35 outpatient clinics reporting, 5.8% of doctor's office visits were due to influenza-like illness. This is the third consecutive week that a decrease has been noted, yet is higher than levels seen during the same week for the previous two seasons (Figure 4).

Which influenza strains are circulating?

Data on influenza virus test results are reported by Chicago laboratories performing influenza subtyping. For the week of January 6-12, 2013, with 6 laboratories reporting, 148 of the 718 (21%) specimens tested for influenza were positive. Among the positive specimens, 142 were typed as influenza A (104 H3N2, 12 H1N1, and 26 were not subtyped) and 6 typed as influenza B (Figure 5). Since September 2012, 1,140 of 6,162 (18.5%) specimens tested for influenza have been positive; 1,107 typed as influenza A (897 H3N2, 65 H1N1, and 145 not subtyped) and 33 typed as influenza B.

Where can I get more information?

The Centers for Disease Control and Prevention's FluView³ report provides national updates and trends related to the intensity of influenza activity across the United States, as well as detailed information on antiviral resistance, severity of illness, and other topics. Updates specific to Illinois⁴ and Suburban Cook County⁵ are also available online. Current and archived issues of the Chicago Flu Update can be found on the CDPH website section Current Flu Situation in Chicago⁶.

National Snapshot (January 6-12,2013)

Viral Surveillance: Of 12,360 specimens tested and reported by collaborating laboratories, 3,638 (29.4%) were positive for influenza.

Pneumonia and Influenza Mortality: The proportion of deaths attributed to pneumonia and influenza (P&I) was above the epidemic threshold.

Influenza-associated Pediatric Deaths: Nine influenzaassociated pediatric deaths were reported.

Influenza-Associated Hospitalizations: A cumulative rate for the season of 18.8 laboratory-confirmed influenza-associated hospitalizations per 100,000 population was reported. Among all cases, 49.6% were in adults 65 years and older.

Outpatient Illness Surveillance: The proportion of outpatient visits for influenza-like illness (ILI) was 4.6%; this is above the national baseline of 2.2%. All 10 regions reported ILI above region-specific baseline levels. Thirty states and New York City experienced high ILI activity; 10 states experienced moderate activity; 7 states experienced low activity; 3 states experienced minimal activity, and the District of Columbia had insufficient data.

Geographic Spread of Influenza: Forty-eight states reported widespread geographic influenza activity; 2 states reported regional activity; the District of Columbia reported local
