EXECUTIVE AND DATA SUMMARY

It's a matter of public health

EXECUTIVE AND DATA SUMMARY

EXECUTIVE SUMMARY

Every Chicagoan should have the opportunity to lead a healthy life. It is the mission of the Chicago Department of Public Health (CDPH) to promote and improve health by engaging residents, communities and stakeholders in establishing services and policies that prioritize residents with the greatest need. We do this work by making data-informed decisions and allocating valuable resources and expertise to where they are needed most.

The annual CDPH HIV/STI Surveillance Report provides CDPH and our many partners in the public health system with the data needed to treat and prevent HIV and other sexually transmitted infections, including chlamydia, gonorrhea, syphilis and congenital syphilis (STIs). The findings of this 2019 report show that HIV continues to disproportionately impact certain groups, including men; gay, bisexual and other men who have sex with men (MSM); and Black communities. The new HIV Services Portfolio (CDPH's enhanced HIV programming) is designed to address challenges and barriers experienced by these groups to ensure all Chicagoans have the opportunity to achieve sexual health and wellness.

The 2019 report also focuses on HIV and STIs in youth and among participants in CDPH's Housing Opportunities for People Living with HIV (HOPWA) program. In Section Three, we present data about the HIV epidemic and STIs among adolescents and young adults aged 13-29 years old. This age group continues to face the highest number of new HIV diagnoses and the highest rate of STIs in Chicago. Section Four presents data for Chicago HOPWA participants, which demonstrates how housing assistance and other supportive services impact HIV health outcomes among people living with HIV (PLWH) at each stage of the HIV Continuum of Care.

DATA SUMMARY

HIV CONTINUUM OF CARE

- In 2018, 81% of persons newly diagnosed with HIV in Chicago were linked to HIV medical care within one month of HIV diagnosis, and 95% of persons newly diagnosed were linked to medical care within 12 months.
- Among all PLWH in 2018, 68% accessed care and 41% were retained in medical care.
- 52% of PLWH in Chicago achieved viral suppression in 2018, an increase when compared to 2017 data (48%).

HIV

- In 2018, a total of 734 new HIV diagnoses were reported among Chicago residents – the lowest number since 1988 – yielding a rate of 27.2 per 100,000 population. This rate represents a 3% decrease compared with 2017 (27.9 cases per 100,000 population) and a 25% decrease compared to 2014 (36.1 cases per 100,000).

EXECUTIVE AND DATA SUMMARY

- A total of 23,580 individuals had been diagnosed with HIV through 2017 and were living with HIV in 2018, yielding a rate of 873.7 per 100,000 population. This rate represents almost a 2% increase in PLWH compared to 2016 (859.4 cases per 100,000 population).
- There were 5.2 times as many new HIV diagnoses in men than in women.
- In 2018, individuals aged 20-29 years old represented 43% of all new HIV diagnoses.
- Non-Hispanic (NH) Blacks represented 55% of new HIV diagnoses, 60% of AIDS diagnoses and 56% of late HIV diagnoses.
- Compared with other HIV transmission groups, there were 3.8 times more new HIV diagnoses among MSM than those reporting heterosexual contact transmission (HET) and 13 times more than those reporting injection drug use (IDU).
- In 2018, the highest rates of new HIV infection diagnoses were seen in individuals residing in Washington Park (76.8 per 100,000), Chatham (64.5 per 100,000) and Grand Boulevard (59.3 per 100,000). The highest rates of PLWH were observed in Uptown (2,004.9 per 100,000), Edgewater (1,886.0 per 100,000) and Rogers Park (1,551.2 per 100,000).

CHLAMYDIA, GONORRHEA, PRIMARY & SECONDARY SYPHILIS AND CONGENITAL SYPHILIS

- In 2018, a total of 30,608 chlamydia cases, 12,679 gonorrhea cases and 877 primary and secondary (P&S) syphilis cases were reported to the CDPH.
- There were 1.4 times as many reported chlamydia cases in women than men, 2.1 times as many reported gonorrhea cases in men than women and 10.5 times as many reported P&S syphilis cases in men than women. MSM continued to account for the majority (81%) of P&S syphilis cases in 2018.
- In 2018, individuals aged 20-29 years old were the most frequently diagnosed group for chlamydia, gonorrhea and P&S syphilis.
- The number of reported STIs was highest among NH Blacks: 44% of reported chlamydia cases, 49% of reported gonorrhea cases and 38% of reported P&S syphilis cases.
- In 2018, the three community areas with the highest chlamydia case rates were Riverdale (2,884.9 per 100,000), Washington Park (2,833.5 per 100,000) and North Lawndale (2,804.1 per 100,000).
- In 2018, the three community areas with the highest gonorrhea case rates were North Lawndale (1,166.7 per 100,000), Riverdale (1,157.1 per 100,000) and Washington Park (1,152.2 per 100,000).
- All community areas with the highest rates of chlamydia and gonorrhea included areas considered to have a high economic hardship. See Appendix D for more information about the Chicago Community Area Economic Hardship Index.
- In 2018, the three community areas with the highest P&S syphilis case rates were Uptown (131.3 per 100,000 population), Washington Park (93.9 per 100,000 population) and Edgewater (90.2 per 100,000 population).
- There were 11 reported cases of congenital syphilis in 2018 in Chicago, similar to 2017.
- NH Black mothers accounted for approximately 73% of the reported congenital syphilis cases in 2018.

SECTION ONE HIV AND STIs IN CHICAGO, 2018

It's a matter of public health

SECTION ONE: HIV AND STIs IN CHICAGO, 2018

HIV

HIV CONTINUUM OF CARE, CHICAGO, 2018

The HIV Continuum of Care is an important tool for monitoring progress and identifying opportunities for HIV prevention, care, treatment and housing interventions. Since ensuring PLWH are engaged in care is critical to both individual and population-level health, the continuum depicts two paths: (1) the percentages of newly diagnosed individuals linked to HIV medical care over the course of one year and (2) the percentages of PLWH at specific levels of care engagement and viral suppression.

In 2018, 81.4% of those newly diagnosed with HIV were linked to HIV medical care within one month of HIV diagnosis. By 12 months post-diagnosis, 94.7% of persons newly diagnosed were linked to medical care. For individuals diagnosed with HIV through 2017 and living with HIV in 2018, 68.0% had accessed medical care (having at least one medical visit in 2018), 41.1% were considered to be retained in care (having at least two medical visits in 2018) and 60.0% had a viral load test in the past 12 months. Reaching viral suppression for PLWH is important to living a high-quality and healthy life and to reducing the likelihood HIV will be transmitted to others. For individuals diagnosed with HIV through 2017 and living with HIV in 2018, 52.0% were considered to be virally suppressed (< 200 copies/mL). The data represented in the continuum illustrate a continuing need to strengthen HIV prevention, care, treatment and housing interventions to ensure that all newly diagnosed PLWH are rapidly linked to medical care and prescribed antiretroviral medications and, once engaged in care, that PLWH have every opportunity to stay in care and achieve viral suppression (Figure 1.1).

HIV IN CHICAGO

In 2018, a total of 734 individuals were newly diagnosed with HIV in the City of Chicago, with a corresponding rate of 27.2 per 100,000 population (Table 1.1) - the lowest ever reported since the late 1980s. However, caution should be taken when comparing 2018 data to previous years as the reduction in new diagnoses may be due to incomplete provider and laboratory reporting. The number of individuals newly diagnosed with AIDS (stage 3 HIV infection) increased by 4.2% from 349 in 2017 to 351 in 2018, though the 2017 and 2018 AIDS case rates were the same - 13.0 per 100,000 population (Table 1.1). Of those newly diagnosed in 2018, a total of 160 individuals were considered to have a late/concurrent diagnosis (individuals were diagnosed with HIV and subsequently AIDS within the 12-month period), which is an increase of 2.6% from 2017 (N=156). This increase in late/concurrent diagnosis signals an opportunity to improve early diagnosis of HIV among people living in Chicago (Table 1.2).

In 2018, a total of 23,580 individuals were diagnosed with HIV through 2017 and living with HIV in 2018, which corresponds to a rate of 873.7 per 100,000 population (Table 1.1). Of those living with HIV in 2018, a total of 12,018 individuals were living with AIDS (Table 1.3).

HIV BY CHICAGO COMMUNITY AREA

In 2018, the three community areas with the highest average HIV infection diagnosis rates were Washington Park (76.8 per 100,000), Chatham (64.5 per 100,000) and Grand Boulevard (59.3 per 100,000) (Figure 1.2; Appendix Table A.1).

SECTION ONE: HIV AND STIs IN CHICAGO, 2018

Similar to previous years, in 2017, the three community areas with the highest HIV prevalence rates were Uptown (2,004.9 per 100,000), Edgewater (1,886.0 per 100,000) and Rogers Park (1,551.2 per 100,000) (Figure 1.3; Appendix Table A.2).

HIV BY SEX/GENDER

In 2018, there were 5.2 times as many new HIV diagnoses in men than women, with 615 cases reported among males and 119 cases reported among females (Table 1.1). The largest number of late diagnoses occurred among males (N=132) when compared to females (N=24), with males accounting for 82.5% of late diagnoses (Table 1.2). New diagnoses among transgender individuals accounted for 3.1% (N=23) of the total 2018 new diagnoses (Table 1.2). While efforts to accurately categorize cases among transgender individuals have improved, estimates of new diagnoses may represent an underestimate.

In 2017, there were 4.2 times as many men living with HIV than women (18,750 males and 4,492 females) (Table 1.3). HIV prevalence among transgender individuals accounted for 1.4% (N=338) of the total Chicago prevalence (Table 1.3). While efforts to accurately categorize cases among transgender individuals have improved, estimates of prevalent cases may represent an underestimate.

HIV BY AGE

In 2018, 36.4% of reported new HIV diagnoses were among persons aged 20-29 years old. This age group also represented the largest percentage of individuals with a late HIV diagnosis, accounting for 51.2% (82/160) of reported late diagnosed cases (Table 1.2).

In 2018, individuals aged 40 years and older accounted for 68.5% of those individuals living with HIV in the City of Chicago (Table 1.3). Individuals aged 20-29 years old (who accounted for the largest number of new diagnoses) only represented 11.8% of those living with HIV in 2018 (Table 1.3).

HIV BY RACE/HISPANIC ETHNICITY

In 2018, NH Blacks were the most frequently diagnosed population, representing 55.2% of new HIV diagnoses, 59.8% of AIDS diagnoses and 55.6% of late diagnoses (Table 1.2). When compared to the next two populations with the largest number of reported cases, there were 2.4 times as many new HIV diagnoses among NH Blacks than among Hispanics and 3.1 times as many new HIV diagnoses than among NH Whites. (Table 1.2).

In 2018, NH Blacks accounted for half (49.9%) of those individuals living with HIV in the City of Chicago (Table 1.3). When compared with the next two populations with the largest number of PLWH, there were 2.1 times more NH Blacks living with HIV than NH Whites living with HIV and 2.5 times more than Hispanics living with HIV (Table 1.3).

HIV BY TRANSMISSION GROUP

In 2018, MSM accounted for the majority (72.2%) of new HIV diagnoses in the City of Chicago (Table 1.2). Compared with other HIV transmission groups, there were 3.8 times more new HIV diagnoses among MSM than those reporting HET and 13.3 than those reporting IDU (Table 1.2).

SECTION ONE: HIV AND STIs IN CHICAGO, 2018

In 2018, MSM represented 63.9% of individuals living with HIV. In comparison to other HIV transmission groups, there were 3.8 times more new HIV diagnoses among MSM than those reporting HET and 13 times more than those reporting IDU (Table 1.3).

CHLAMYDIA

CHLAMYDIA IN CHICAGO

Chlamydia, a sexually transmitted bacterial infection caused by *Chlamydia trachomatis*, is the most common notifiable disease in the United States. According to the CDC 2018 STD Surveillance Report, chlamydia is one of the most prevalent STIs and has comprised the largest proportion of all STIs reported to CDC since 1944. In 2018, a total of 30,608 chlamydia cases were reported in the City of Chicago (Table 1.4). This case count corresponds to a rate of 1,135.5 per 100,000 population (Table 1.1).

CHLAMYDIA BY CHICAGO COMMUNITY AREA

In 2018, the rates of reported cases of chlamydia ranged from 178.3 to 2,884.9 per 100,000 population throughout the City of Chicago (Figure 1.4). The three community areas with the highest average chlamydia case rates from in 2018 were Riverdale (2,884.9 per 100,000), Washington Park (2,833.5 per 100,000) and North Lawndale (2,804.1 per 100,000) (Figure 1.4; Appendix Table A.3).

CHLAMYDIA BY SEX

In 2018, there were 1.4 times as many reported chlamydia cases in women than men, with 17,933 cases reported among females and 12,672 cases reported among males (Table 1.4). This disparity between the sexes is consistent with previous years and likely reflects a larger number of females screened for this infection. It is also likely that many of the sex partners of women with chlamydia did not receive a diagnosis nor were they reported as having chlamydia infections.

CHLAMYDIA BY AGE

The number of reported cases of chlamydia were highest among adolescents and young adults aged 13- 29 years old. In 2018, individuals aged 20-29 years old represented 54.0% of all reported chlamydia cases (Table 1.4). If this group were combined with those aged 13-19 years old, individuals 13 to 29 years represented 78.6% of all reported chlamydia cases in 2018 (Table 1.4).

CHLAMYDIA BY RACE/HISPANIC ETHNICITY

In 2018, NH Blacks were the most frequently diagnosed population, representing 43.6% of reported chlamydia cases in Chicago (Table 1.4). When compared to the next two populations with the largest number of reported cases, there were 2.8 times as many chlamydia cases in NH Blacks compared to Hispanics and 4.7 times as many compared to NH Whites (Table 1.4).

CHLAMYDIA + HIV CO-INFECTION

In 2018, a total of 1,297 (4.2%) reported chlamydia cases were also co-infected with HIV (Table 1.5). The majority of co-infected individuals were male (93.2%), NH Black (44.8%), aged 20-29 years old (35.6%) and MSM (66.9%) (Table 1.5).

GONORRHEA

GONORRHEA IN CHICAGO

Gonorrhea, a sexually transmitted bacterial infection caused by *Neisseria gonorrhoeae*, is the second most commonly reported notifiable disease in the United States and Chicago. In 2018, a total of 12,679 gonorrhea cases were reported in the City of Chicago (Table 1.1). This case count corresponds to a rate of 470.4 per 100,000 population (Table 1.1).

According to the CDC 2018 STD Surveillance Report, gonorrhea infections, like those resulting from *Chlamydia trachomatis*, are a major cause of pelvic inflammatory disease (PID) in the United States which can lead to serious outcomes among women, such as tubal infertility, ectopic pregnancy and chronic pelvic pain. In addition, epidemiologic and biologic studies provide evidence that gonococcal infections facilitate the transmission of HIV infection. Also of concern, *Neisseria gonorrhoeae* has progressively developed resistance to many of the antimicrobials used for treatment of gonorrhea.

GONORRHEA BY CHICAGO COMMUNITY AREA

In 2018, the rates of reported cases of gonorrhea ranged from 31.4 to 1,166.7 per 100,000 population throughout the City of Chicago (Figure 1.5). The three community areas with the highest average gonorrhea case rates in 2018 were North Lawndale (1,166.7 per 100,000), Riverdale (1,157.1 per 100,000) and Washington Park (1,152.2 per 100,000) (Figure 1.5; Appendix Table A.4).

GONORRHEA BY SEX

As in previous years, the number of reported gonorrhea cases among males was 2.1 higher than among females in 2018. In total, 8,616 cases were reported among males and 4,063 cases among females (Table 1.4). The magnitude of diagnoses among males suggests either increased transmission or increased case ascertainment (e.g., through increased extra-genital screening among MSM). As most providers do not routinely report sex of sex partners or site of infection for gonorrhea cases, trends in gonorrhea diagnoses among MSM cannot be assessed.

GONORRHEA BY AGE

Similar to reported cases of chlamydia, gonorrhea cases in Chicago continued to be highest among adolescents and young adults. In 2018, individuals aged 20-29 years old were the most frequently diagnosed age group, representing 51.4% of all reported gonorrhea cases (Table 1.4). If this group were combined with those aged 13-19 years old, individuals 13-29 years represent 69.2% of all reported gonorrhea cases in 2018 (Table 1.4).

GONORRHEA BY RACE/HISPANIC ETHNICITY

In 2018, the number of reported gonorrhea cases remained highest among NH Blacks, with 49.0% of reported cases in Chicago (Table 1.4). When compared to the next two populations with the largest number of reported cases, there were 4.0 times as many gonorrhea cases in NH Blacks compared to Hispanics and 3.5 times as many compared to NH Whites (Table 1.4).

SECTION ONE: HIV AND STIs IN CHICAGO, 2018

GONORRHEA + HIV CO-INFECTION

In 2018, a total of 1,546 (12.1%) reported gonorrhea cases were also co-infected with HIV (Table 1.5). The majority of co-infected individuals were male (97.7%), NH Black (48.6%), aged 20-29 years old (38.7%) and MSM (67.3%) (Table 1.5).

PRIMARY & SECONDARY (P&S) SYPHILIS

P&S SYPHILIS IN CHICAGO

P&S syphilis are the most infectious stages of the infection that reflect symptomatic disease and are used as indicators of new infection. In 2018, a total of 877 P&S syphilis cases were reported in the City of Chicago (Table 1.1). This case count corresponds to a rate of 32.5 per 100,000 population (Table 1.1).

P&S SYPHILIS BY CHICAGO COMMUNITY AREA

In 2018, the rates of reported cases of P&S syphilis ranged from 9.7 to 131.3 per 100,000 population throughout the City of Chicago (Figure 1.6). The three community areas with the highest average P&S syphilis case rates in 2018 were Uptown (131.3 per 100,000 population), Washington Park (93.9 per 100,000 population) and Edgewater (90.2 per 100,000 population) (Figure 1.6; Appendix Table A.4).

P&S SYPHILIS BY SEX

In 2018, the number of reported P&S syphilis cases among men was 10.5 times higher than among females, with 800 cases reported among males and 76 cases reported among females (Table 1.4). MSM continued to account for the majority of P&S syphilis cases in 2018, representing 709 of the 877 reported cases.

P&S SYPHILIS BY AGE

In 2018, individuals aged 20-29 years old were the most frequently diagnosed age group, representing 37.9% of all reported P&S syphilis cases (Table 1.4). However, unlike reported chlamydia and gonorrhea cases, older age groups also made up large percentages of reported P&S syphilis cases, with individuals aged 30-39 representing 30.7% and individuals 40-49 representing 16.0% of all reported cases (Table 1.4).

P&S SYPHILIS BY RACE/HISPANIC ETHNICITY

Like with other reportable STIs, NH Blacks were the most frequently diagnosed population, representing 38.3% of reported P&S syphilis cases in Chicago in 2018 (Table 1.4). When compared to the next two populations with the largest number of reported cases, there were 1.7 times as many P&S syphilis cases in NH Blacks compared to Hispanics and 1.4 times as many compared to NH Whites (Table 1.4).

P&S SYPHILIS BY TRANSMISSION GROUP

According to the 2018 CDC STD Surveillance Report, MSM accounted for the majority of reported P&S syphilis cases in 2018 in the United States. Similarly in Chicago, the largest proportions of P&S syphilis cases (80.8%) were among MSM, while men who have sex with females represent 1.4% of

SECTION ONE: HIV AND STIs IN CHICAGO, 2018

the cases (Table 1.4). Notably, 9.0% of male syphilis cases were reported among males whose sexual orientation was unknown, which, if known, could potentially increase the number of cases among MSM.

P&S SYPHILIS + HIV CO-INFECTION

In 2018, a total of 310 reported P&S syphilis cases (35.3%) were also co-infected with HIV (Table 1.5). The majority of co-infected individuals were male (97.4%), NH Black (42.9%), aged 30-39 years old (36.8%) and MSM (71.9%) (Table 1.5).

CONGENITAL SYPHILIS

CONGENITAL SYPHILIS IN CHICAGO

If an early syphilis infection is left untreated in a pregnant woman, it can lead to congenital syphilis which can cause infection of the fetus and increase the risk for stillbirth or death of the infant. Similar to the previous year, in 2018, there were only 11 congenital syphilis cases reported in Chicago (Table 1.6). In 2018, CDPH launched two media campaigns in the areas with the highest incidence of P&S syphilis among females in Chicago.

CONGENITAL SYPHILIS BY CHICAGO COMMUNITY AREA

From 2014 to 2018, the average annual rates of reported cases of congenital syphilis ranged from 0 to 714.3 per live births throughout the City of Chicago. The Chicago community area with the highest average congenital syphilis case rate from 2014 to 2018 was Fuller Park, which is considered an area of high economic hardship (Figure 1.7).

CONGENITAL SYPHILIS BY MATERNAL AGE

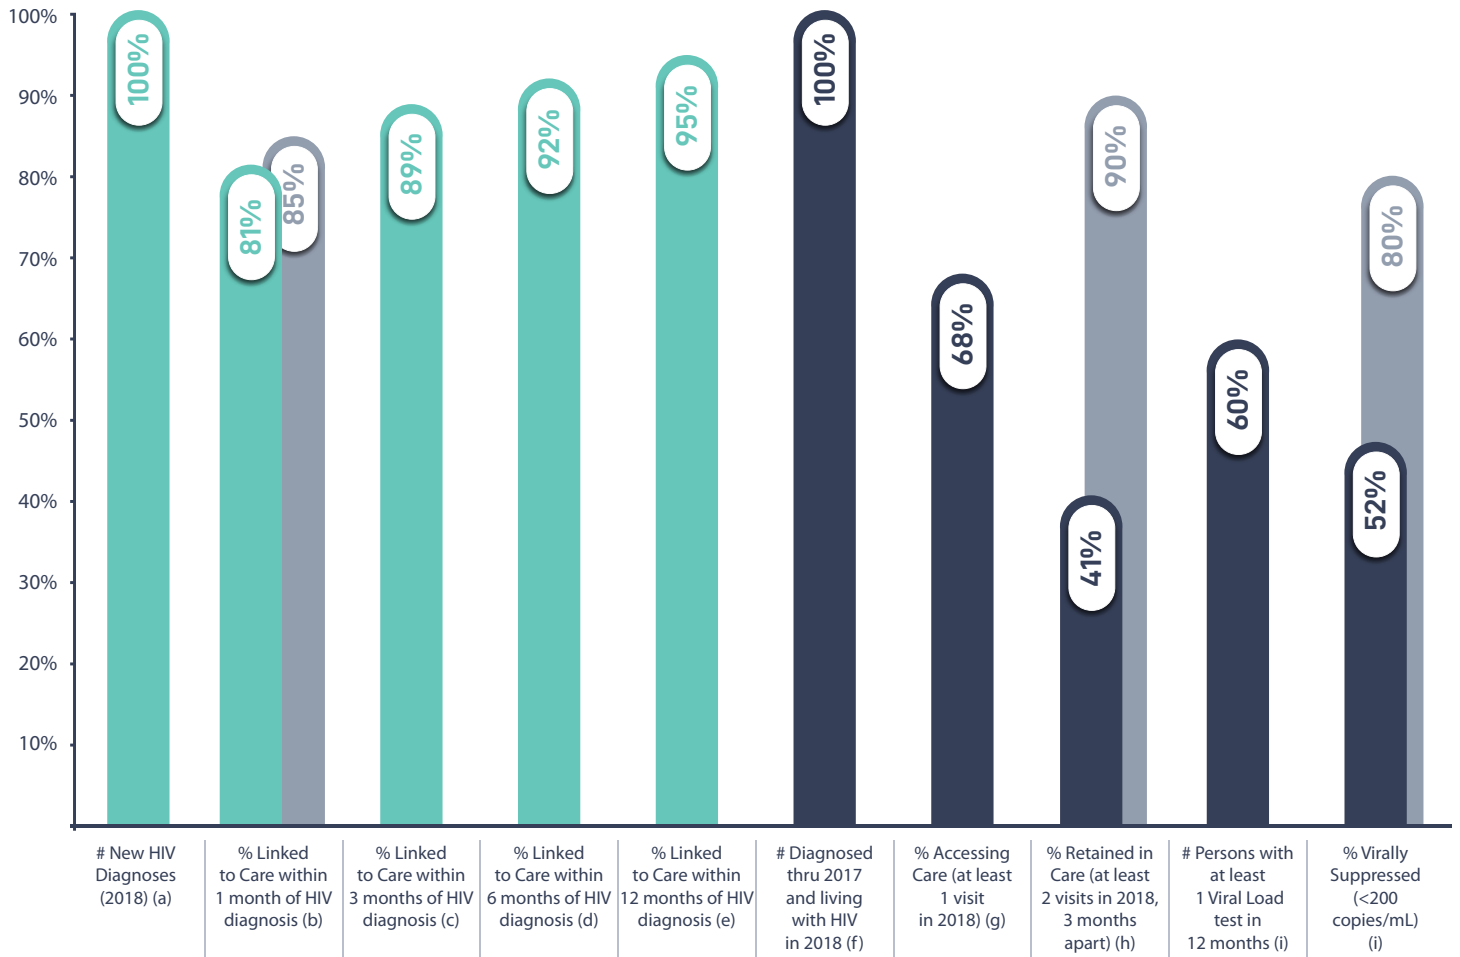

In 2018, mothers aged 20-29 accounted for 54.5 % of the congenital syphilis cases in the City of Chicago (Table 1.6). This age group has accounted for the majority of congenital syphilis cases for the past five years. The median maternal age for congenital syphilis cases in 2018 was 28 years old, an increase from the median age of 25 years in 2017 (Table 1.6).

CONGENITAL SYPHILIS BY RACE/ETHNICITY

As in previous years, in 2018, the highest proportion of the congenital syphilis cases were among NH Blacks (72.7%) followed by Hispanics (18.2%) while less than 10% of cases were among NH Whites (Table 1.6).

SECTION TWO TRENDS IN HIV AND STIs IN CHICAGO, 2014-2018

It's a matter of public health

SECTION TWO: TRENDS IN HIV AND STIs IN CHICAGO, 2014-2018

Trends in People Living With and Diagnosed With HIV Infection in Chicago

From 1990-2018, there has been an annual increase in the number of PLWH in Chicago. In 2017, 23,580 PLWH resided in Chicago. This is approximately 4.4 times the number of PLWH in Chicago in 1990 (Figure 2.1).

In 2018, the number of newly diagnosed HIV cases reported to CDPH was below 800 for the second year in a row with 734 cases. Caution should be taken when interpreting the drop in cases over the last two years as this could be related to the reporting delays.

The proportion of newly diagnosed HIV infections and distribution of cases among males and females has remained relatively consistent from 2014-2018, with a majority of cases occurring among men (Table 2.1). Comparing 2017 newly diagnosed HIV cases with 2018 newly diagnosed HIV cases, all age groups had a percent decrease in newly diagnosed HIV infections, except for those 40 years of age and older (Table 2.2). From 2014-2018, the largest proportion of HIV infection diagnoses occurred among NH Blacks (Table 2.3), with 405 cases accounting for 55.2% of the reported 2018 cases. Over the five year span, the distribution of cases among racial/ethnic categories has remained relatively stable (Table 2.3).

Trends in the Number of Reported STIs in Chicago

CHLAMYDIA: The number of chlamydia cases (30,608 cases) reported in 2018 is the highest since 1997 (Figure 2.2). Since 2014, chlamydia cases have increased by 12.2% (27,274 to 30,608) (Table 2.1). While there has been a steady increase in the proportion of reported chlamydia cases in males from 2014-2018, women continue to have the highest number of cases with 1.4 times as many reported chlamydia cases in women than men in 2018 (Table 2.1).

GONORRHEA: Between 2014 and 2018, the total number of gonorrhea cases increased by 53% (8,291 to 12,679) (Table 2.1). Targeted and extra-genital STI screening among MSM may have contributed, in part, to the overall increase in the number of reported gonorrhea cases in recent years.

PRIMARY & SECONDARY SYPHILIS: Similar to chlamydia and gonorrhea, between 2014 and 2018, the total number of reported P&S syphilis cases increased by 36.4% (from 643 to 877), mostly among males (Table 2.1).

TRENDS BY AGE: As has been observed in previous years, in 2018, individuals aged ≤ 29 years old made up a majority (78.6%) of reported chlamydia cases. This is also true for gonorrhea (69.3%), but case reports are rising in all age groups except 13-19 year olds. This increase in reported gonorrhea cases in older age groups may be a result of increased testing efforts by providers and increased STI awareness in specific population groups, such as MSM. As with chlamydia and gonorrhea, reported P&S syphilis cases have increased across all age categories with the exception of the <13 age group as compared to 2014. The majority of 2018 cases are seen in ages 20-29 (37.9%) (Table 2.2).

SECTION TWO: TRENDS IN HIV AND STIs IN CHICAGO, 2014-2018

TRENDS BY RACE/HISPANIC ETHNICITY: Similar to HIV trends over the last five years, the highest proportion of chlamydia, gonorrhea and P&S syphilis cases were among NH Blacks followed by NH Whites for gonorrhea and P&S syphilis and Hispanics for chlamydia (Table 2.3). Hispanics account for the second highest proportion of chlamydia cases from 2014 to 2018 going from 12.1% of the cases in 2014 to 15.8% of the cases in 2018 (Table 2.3). Hispanics comprise the third highest proportion of cases for P&S syphilis with 16.0% of the cases in 2014 and 22.8% of the cases in 2018 (Table 2.3).

FIGURE 2.1: People Living with HIV Infection, People Diagnosed with HIV Infection, People Diagnosed with AIDS, Concurrent HIV/AIDS Diagnoses and Deaths Among People Living with HIV Infection, Chicago, 1990-2018 (as of 10/01/2019)

Notes on Surveillance Reporting:
 1983 = AIDS case reporting begins
 1995 = Effective drug therapy against HIV becomes available

1999 = Code-based HIV reporting begins
 2006 = Name-based HIV reporting begins
 2012 = All CD4 and viral load labs become reportable

SECTION
THREE
HIV AND STIs
IN YOUTH

It's a matter of public health

SECTION THREE: HIV AND STIs IN YOUTH

HIV

According to the CDC 2018 HIV Surveillance Report, individuals aged 13-29 years old accounted for 41.1% of new HIV diagnoses in 2018 in the United States. Approximately 10.3% of the PLWH in 2018 were aged 13-29 years old.

In Chicago, 321 cases of HIV infection were diagnosed among individuals aged 13-29 years old in 2018, accounting for 43.7% of all new HIV infection diagnoses (Table 3.1). The majority of cases were among males (81.9%), NH Blacks (62.9%) and MSM (80.4%) (Table 3.1). Between 2014 and 2018, the number of new HIV diagnoses in this population decreased by 28.2%, from 447 cases diagnosed in 2014 to 321 cases diagnosed in 2018 (Table 3.1). From 2014-2018, the highest average annual rate of HIV diagnoses among those aged 13-29 years old was observed in Uptown (26.8 per 100,000 population), Greater Grand Crossing (25.9 per 100,000 population) and East Garfield Park (24.9 per 100,000 population) (Figure 3.1; Appendix Table A.6).

In 2017, 3,024 people aged 13-29 years old were living with HIV in Chicago, accounting for 12.8% of all individuals living with HIV in the city (Table 3.2). The majority of these individuals were male (78.8%), NH Black (68.7%) and MSM (73.7%) (Table 3.2). Between 2013 and 2017, the number of individuals aged 13-29 years old living with HIV increased by 9.4% from 2,764 in 2013 to 3,024 in 2017 (Table 3.2). From 2013-2017, the highest average annual rate of individuals aged 13-29 years old living with HIV was observed in South Shore (215.1 per 100,000 population), Washington Park (203.6 per 100,000 population) and Greater Grand Crossing (194.7 per 100,000 population) (Figure 3.2; Appendix Table A.7).

In 2017, 85.6% of those diagnosed with HIV aged 13-29 years old were linked to HIV medical care within one month of HIV diagnosis (Figure 3.3). By 12 months after diagnosis, 95.4% had been linked to medical care (Figure 3.3). For individuals aged 13-29 years old who were diagnosed with HIV through 2017 and living with HIV in 2018, 95.4% had accessed medical care (having at least one medical visit in 2017), 82.6% were considered to be retained in care (having at least two medical visits in 2017) and 93.4% had a viral load test in the past 12 months (Figure 3.3). For this group, only 63.6% were considered to be virally suppressed (< 200 copies/ mL), indicating an opportunity to strengthen programs and services for younger populations (Figure 3.3).

STIs

According to the CDC 2018 STD Surveillance Report, incidence and prevalence estimates suggest that young people aged 15-24 years old acquire half of all new STIs, and that one in four sexually-active adolescent females has an STI. Consistent with national data, STI rates among adolescents and young adults in Chicago are acquiring 50% or more of newly reported STIs. In 2018, 24,045 (78.5%) cases of chlamydia, 8,744 (69.0%) cases of gonorrhea and 368 (42.0%) cases of P&S syphilis were diagnosed among those aged 13-29 years old. Between 2014 and 2018 in Chicago, the total number of cases diagnosed in this population has been steadily increasing across all reportable STIs: 4.8% increase in chlamydia cases, 36.3% increase in gonorrhea cases and a 30.0% increase in P&S syphilis cases (Table 3.3; Table 3.4; Table 3.5).

SECTION THREE: HIV AND STIs IN YOUTH

As shown in Table 3.3, the proportion of chlamydia cases in 2018 among those aged 13-29 years old was highest among females (64.2%) and NH Blacks (47.8%). Gonorrhea cases in 2018 in this age group were highest among males (60.6%) and NH Blacks (55.4%) (Table 3.4). For P&S syphilis, there were 8.4 times as many P&S syphilis cases in 2018 among men (89.1%) in this population than women (89.1% vs. 10.6%), reflecting the overall epidemiology of P&S syphilis in Chicago (Table 3.5). Like chlamydia and gonorrhea, NH Blacks aged 13-29 years old represented the largest share of new P&S syphilis cases in 2018 (48.1%), followed by Hispanics (24.2%).

SECTION FOUR HOUSING OPPORTUNITIES FOR PLWH (HOPWA) PROGRAM

It's a matter of public health

SECTION FOUR: HOUSING OPPORTUNITIES FOR PLWH (HOPWA) PROGRAM

Background

Housing has been shown to be an important social determinant of physical and mental health and well-being (Maqbool, N; Viveiros, J; Ault, M, 2015). Affordable and stable housing can help lead to better health outcomes among low-income populations by reducing the risk of mental illness, physical disease and disability, limiting stressors related to financial burden or frequent moves, as well as allowing individuals and families to spend more of their income on paying for healthcare and healthy foods (Milloy, M.J.; et al., 2012), (Maqbool, N; Viveiros, J; Ault, M, 2015). In addition to these co-health benefits, housing assistance for PLWH is linked to improved HIV prevention, treatment access and retention in HIV care, and a reduction in behaviors that can transmit HIV to others (Kidder, D P; Wolitski, R J; Campsmith, M L, 2007a), (Lennon, C A; et al., 2013).

What do we do

Since 1992, CDPH has served as the United States Department of Housing and Urban Development (HUD) - HOPWA formula grantee for the Chicago Eligible Metropolitan Statistical Area (EMSA). The Chicago EMSA is comprised of seven counties (Cook, DeKalb, DuPage, Grundy, Kendall, McHenry, and Will), with a 2017 estimated population of 7.4 million, representing 58% of the population of the state of Illinois.

CDPH's HOPWA program addresses the specific housing needs of PLWH by funding not-for-profit, community-based organizations located within the Chicago EMSA to prevent homelessness and facilitate access to a range of needed care, treatment and supportive services. The HOPWA program funds three service categories:

- **Facility-Based Housing Assistance** funds residential facilities (e.g., community residences, single-room-occupancy dwellings, short-term facilities, project-based rental units and master-leased units) and multiple apartments within the same building or building complex that houses PLWH and their families. This program also provides access to supportive services for clients and their beneficiaries.
- **Tenant-Based Rental Assistance** is a rental subsidy program used to help low-income households obtain permanent housing in the private rental housing market that meets housing quality standards and is rent-reasonable. This program also provides access to supportive services for clients and beneficiaries.
- **Housing Information Services** are intended for low-income PLWH and their families who are homeless or in imminent danger of becoming homeless that are not currently in HOPWA-supported housing. The program assists in locating, acquiring and maintaining housing. Services may also include referral to legal assistance for eviction issues, mediation, adoption, acquiring social security benefits and other federal assistance and wrongful discharge.

SECTION FOUR: HOUSING OPPORTUNITIES FOR PLWH (HOPWA) PROGRAM

CDPH HOPWA Program Goal and Objectives

Goal – Provide housing for PLWH.

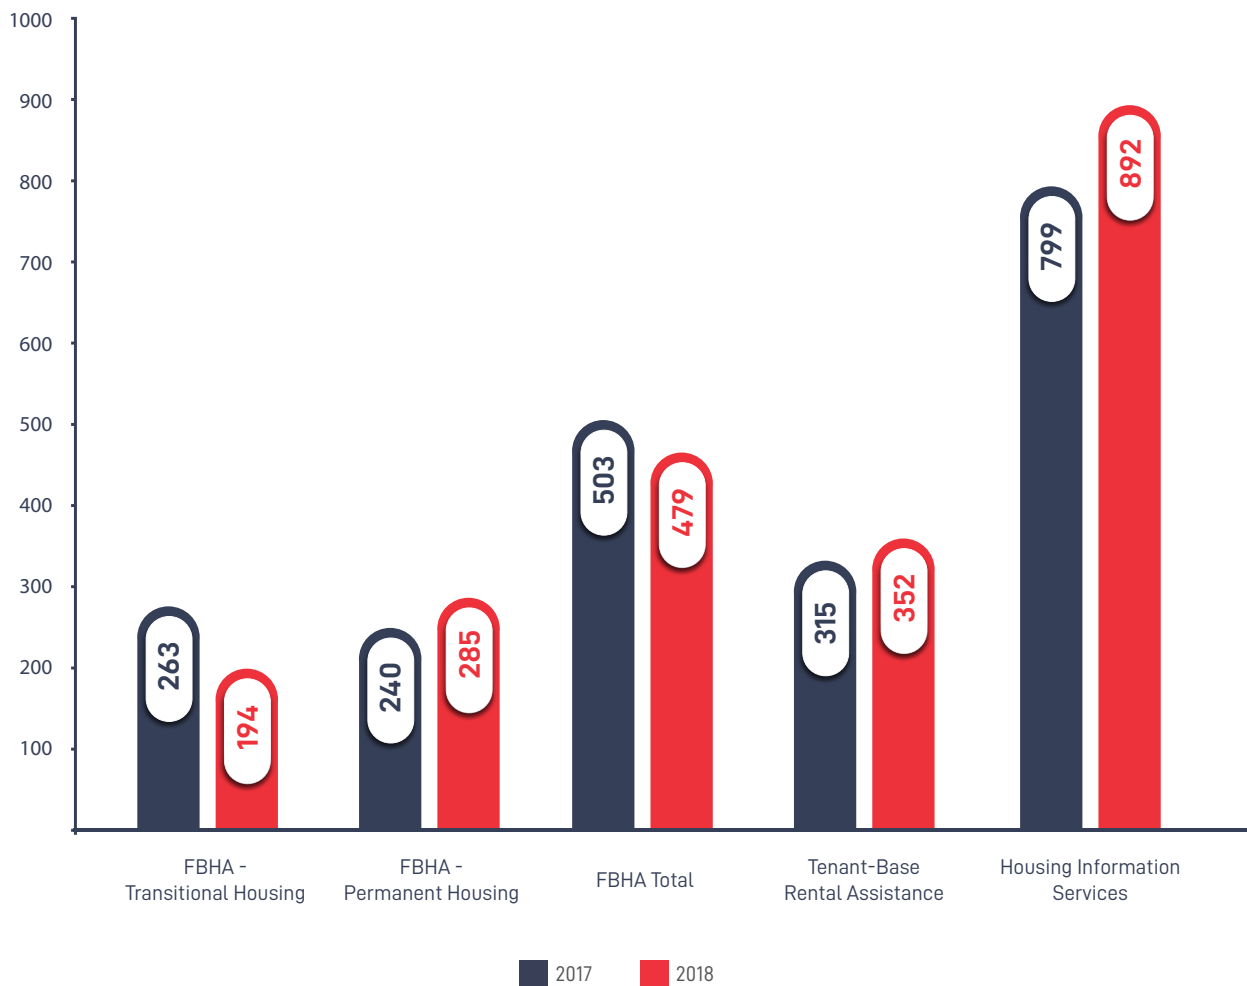

Objective 1.1 – Provide Facility-Based Housing Assistance to a minimum of 467 low-income PLWH in the Chicago EMSA.

Objective 1.2 – Provide Housing Information Services to a minimum of 787 low-income PLWH in the Chicago EMSA.

Objective 1.3 – Provide Tenant-Based Rental Assistance to a minimum of 334 low-income PLWH in the Chicago EMSA.

CDPH HOPWA Program Performance

Figure 4.1: Total Number of HOPWA Clients who Received Facility-Based Services, Tenant-Based Services and/or Housing Information Services, Chicago EMSA, 2017 and 2018

HIV Continuum of Care: HOPWA Clients vs. Chicago EMSA, 2017

Since 2015, CDPH has been collaborating with HOPWA-funded agencies in the Chicago EMSA to collect client-level data to track medical outcomes along the HIV Care Continuum. The purpose of this evaluation is to evaluate the health outcomes of HOPWA clients utilizing the HIV Care Continuum, among those who received housing assistance from January 1, 2017 through December 31, 2017.

Methods

Sixteen HOPWA-funded organizations submitted 2016-2017 client rosters (N=1,409) to CDPH via a secure file transfer protocol (sFTP). Rosters consisted of client's first name, last name, date of birth, gender, HOPWA intake and exit date and housing model. Of the client rosters, 1,094 (60.4%) HOPWA clients receiving housing assistance during January 1, 2017 through December 31, 2017 were eligible for this evaluation. Using client's first name, last name and date of birth, 1,058 HOPWA clients were matched to CDPH's enhanced HIV/AIDS Reporting System (eHARS). Of those, 170 were removed from the sample due to duplicate eHARS unique identifiers. For this evaluation, 888 (81%) unduplicated HOPWA clients were then evaluated for linkage to care, accessing care, retention in care and viral suppression using the CDC National HIV/AIDS Strategy (NHAS) indicator program. Among those matched cases, 75% were male, 63.2% were aged 45 years and older, 65.5% were NH Black and 44.1% were MSM (Table 4.1).

Date of diagnosis was obtained from eHARS. Linkage to care was assessed among individuals who were 13 years of age at diagnosis, resided in Chicago EMSA (based on most recent residence), diagnosed with HIV infection between January 1, 2017 and December 31, 2017, and defined as having one medical care visit with a provider within three, six or 12 months of diagnosis. Accessing care, retention in care and viral suppression were assessed among individuals who were 13 years of age at diagnosis, resided in Chicago EMSA (based on most recent residence) and diagnosed with HIV infection through December 31, 2016 and living with HIV on December 31, 2017. Accessing care was defined as one medical care visit between January 1, 2017 and December 31, 2017. Individuals were considered retained in care if they had had two medical care visits at least three months apart between January 1, 2017 and December 31, 2017. Viral suppression was defined as having a viral load <200 copies/mL between January 1, 2017 and December 31, 2017. Matching and analyses were performed using SAS version 9.4.

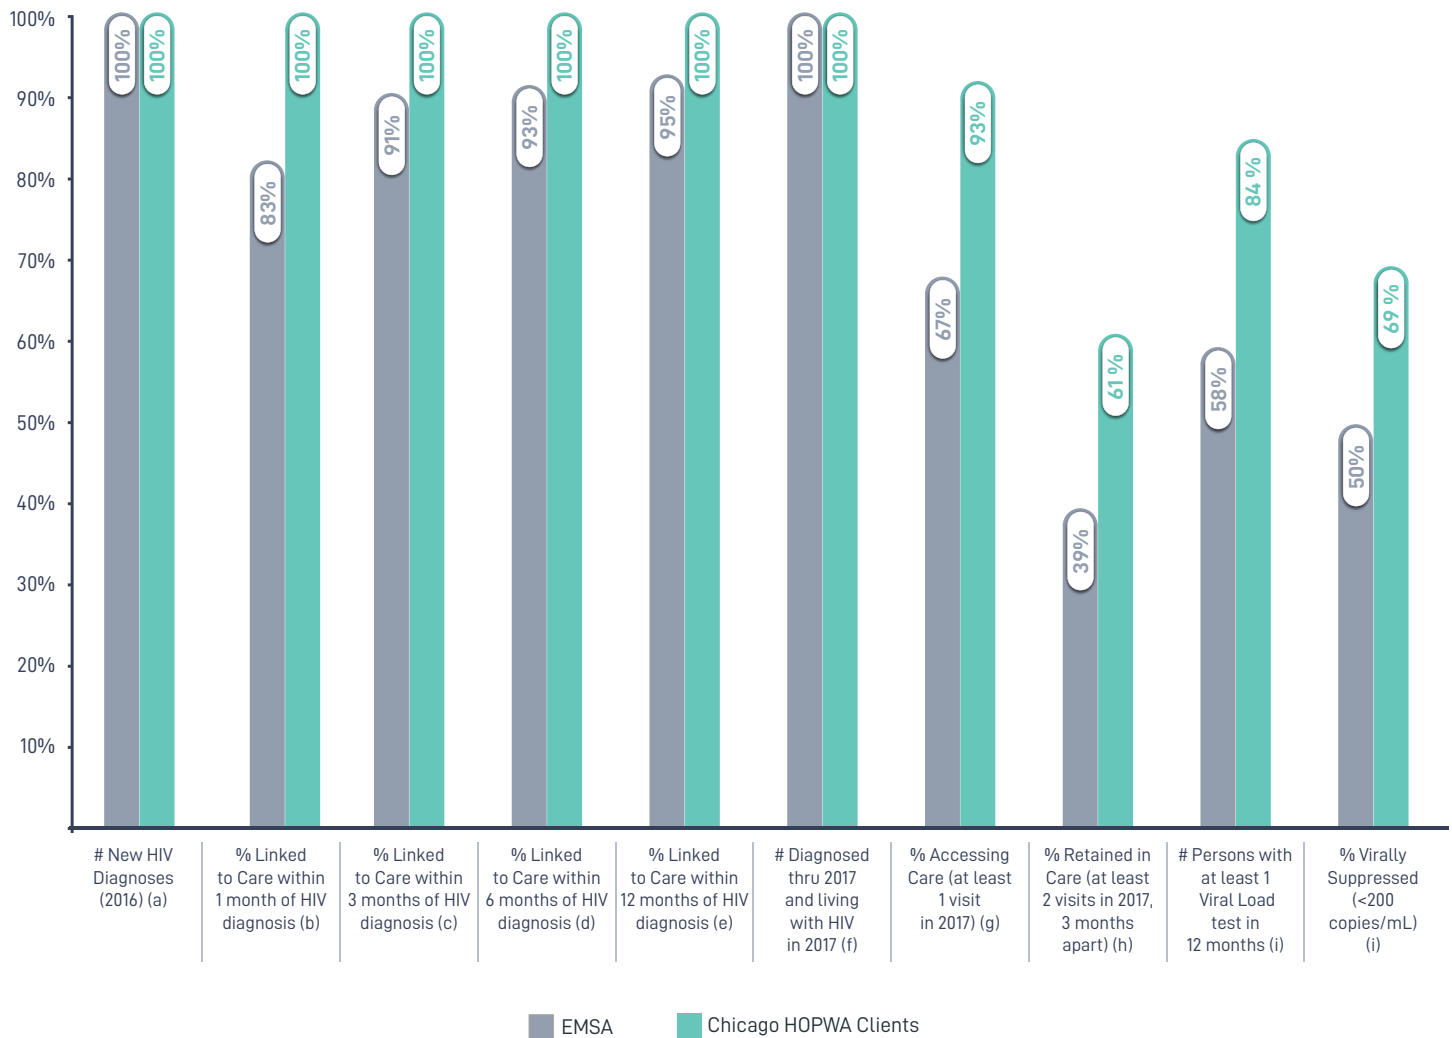

SECTION FOUR: HOUSING OPPORTUNITIES FOR PLWH (HOPWA) PROGRAM

Table 4.1: Demographic Characteristics of HOPWA Clients Who Received Housing Assistance and Supportive Services in 2017, Chicago EMSA

Characteristics	Matched HOPWA Clients

Results

Figure 4.2 compares the 2017 HIV Continuum of Care for CDPH HOPWA clients and all PLWH in the Chicago EMSA. In 2017, 100% of HOPWA clients were linked to HIV medical care within one month of HIV diagnosis, as compared to 83% for the Chicago EMSA overall. For HOPWA clients who were diagnosed with HIV through December 31, 2016 and living with HIV in December 31, 2017, 93% accessed medical care, 61% were retained in care, 84% had a viral load test in the previous 12 months and 69% attained viral suppression. PLWH in the Chicago EMSA who were not HOPWA clients had much lower percentages across these categories.

Figure 4.3 breaks out the 2017 HIV Continuum of Care by HOPWA clients who received facility-based services, HOPWA clients who received tenant-based services and all PLWH in the Chicago EMSA. In 2017, 100% of HOPWA clients diagnosed with HIV were linked to HIV medical care within one month of HIV diagnosis, as compared to 83% for the Chicago EMSA. For HOPWA clients who were diagnosed with HIV through December 31, 2016 and living with HIV in December 31, 2017 and received facility-based housing assistance, 94% accessed medical care, 61% were retained in care, 86% had a viral load test in the past 12 months and 69% attained viral suppression. For HOPWA clients who were diagnosed with HIV through December 31, 2016 and living with HIV in December 31, 2017 and received tenant-based housing assistance, the results were very similar: 91% accessed medical care, 60% were retained in care, 82% had a viral load test in the past 12 months and 70% attained viral suppression. Outcomes for HOPWA clients, regardless of service type, were much better than for the general population PLWH in the Chicago EMSA.

Discussion

This evaluation provides the CDPH HOPWA program with the ability to monitor the HIV health outcomes of PLWH who use HOPWA services along each step of the continuum. Results of this analysis are consistent with previous studies that have demonstrated a link between housing assistance and improved HIV health outcomes among PLWH. The data also suggest that CDPH HOPWA-funded programs have opportunities to strengthen programming to better support ongoing retention in care, prescribing of antiretroviral medications and viral suppression.

APPENDICES

It's a matter of public health

APPENDICES

Appendix A: Technical Notes - General

As the HIV epidemic and HIV reporting systems change, new opportunities arise to better describe the epidemic. Thus, in keeping with these changes we have made a number of modifications to STI/HIV Chicago. A description of the changes and other technical notes follow.

Diagnoses data are presented through 2018. While STI data are final, AIDS and HIV data for 2018 are still provisional.

HIV/AIDS

When interpreting data in this report, keep in mind that the eHARS database is updated continuously to reflect the most current and complete information on people infected and newly diagnosed with HIV or AIDS; data in this report were up-to-date as of 10/01/2019. Reporting delays are important when interpreting trends in case numbers and rates over time, especially with the most recent year of diagnosis. Report delay is defined as the interval between the date an HIV or AIDS case is diagnosed and the date the case is reported to the health department. Within three years, the total number of HIV diagnoses reported are relatively stable (fluctuating < 10 cases) and the data are no longer considered provisional. In order to provide the most complete data as possible, we will be presenting trend data through 2018. Additional cases continue to be reported in subsequent years and new cases are identified through laboratory reporting and registry matches. Thus, the numbers of cases diagnosed for each year are subject to change as new information is received from any of the reporting sources.

The "HIV Infection Diagnosis" data presented in this issue include three categories of diagnoses: (1) a diagnosis of HIV infection, (2) a diagnosis of HIV infection with a later diagnosis of AIDS, and (3) concurrent diagnoses of HIV infection and AIDS [defined as receiving an AIDS diagnosis within 12 months of an HIV diagnosis]. Data from the HIV reporting system should be interpreted with caution. HIV surveillance reports may not be representative of all persons infected with HIV because not all infected persons have been tested. The guidelines for cell suppression used in this report try to balance data accessibility with confidentiality and confidence in the stability of the estimates published. Rates and percentages based on 20 or fewer cases can vary widely just by random chance even when there is no meaningful statistical difference between measurements. Thus, the number and rate for categories with less than five are suppressed.

For surveillance purposes, HIV and AIDS cases are counted only once in a hierarchy of modes of transmission. Persons with more than one reported mode of transmission are classified in the transmission mode first in the hierarchy. The exception is men who have sex with men and also inject drugs, which has its own category. Persons whose transmission mode is classified as male-to-male sexual contact (MSM) include men who report sexual contact with other men and men who report sexual contact with both men and women. Persons whose mode of transmission is classified as heterosexual contact are persons who report specific heterosexual contact with a person with, or at increased risk for, HIV infection (e.g., an injection drug user).

APPENDICES

Because many cases of HIV infection and AIDS are initially reported without a defined mode of transmission, we use multiple imputation to assign a mode of transmission for these cases. Multiple imputation is a statistical approach in which each missing mode of transmission is replaced with a set of plausible values that represent the uncertainty about the true, but missing, value. The plausible values are analyzed by using standard procedures, and the results from these analyses are then combined to produce the final results. Multiple imputation is used by the Centers for Disease Control and Prevention (CDC) in their national HIV Surveillance Report.

GONORRHEA

Gonorrhea is one of three sexually transmitted infections (STIs) that local providers are required to report to CDPH per 77 Illinois Administrative Code 693 (Control of sexually transmissible infections code). Gonorrhea is a bacterial STI caused by *Neisseria gonorrhoeae*; infection varies in course, severity and symptoms among males and females (Heymann, 2004). Co-infection with chlamydia can occur. Left untreated, disease sequelae can include pelvic inflammatory disease (PID), ectopic pregnancy and infertility. *Neisseria gonorrhoeae* has progressively developed resistance to each of the antibiotics used for treatment of gonorrhea. Most recently, declining susceptibility to cefixime resulted in a change in the CDC treatment guidelines, so that dual therapy with ceftriaxone and either azithromycin or doxycycline is now a CDC recommended treatment regimen for gonorrhea.

CHLAMYDIA

Chlamydia trachomatis infection is the most commonly reported notifiable disease and is one of three STIs that local providers are required to report to CDPH per 77 Illinois Administrative Code 693 (Control of sexually transmissible infections code). Chlamydial infections in women are usually asymptomatic. However, these can result in pelvic inflammatory disease (PID), which is a major cause of infertility, ectopic pregnancy and chronic pelvic pain. In addition, pregnant women infected with chlamydia can pass the infection to their infants during delivery, potentially resulting in neonatal ophthalmia and pneumonia. Because of the large burden of disease and risks associated with infection, CDC recommends that all sexually active women younger than age 26 receive annual chlamydia screening.

SYPHILIS

Syphilis is one of three STIs that local providers are required to report to CDPH per 77 Illinois Administrative Code 693 (Control of sexually transmissible infections code). Syphilis is caused by a bacteria called *Treponema Pallidum*. Syphilis, a genital ulcerative disease, causes significant complications if untreated and facilitates the transmission of HIV infection. Syphilis is characterized by stages: primary (can have a lesion known as a chancre, usually occurring three weeks post exposure), secondary (symptoms include rash and fatigue), early latent (less than one year post exposure) and late latent (greater than one year post exposure). Primary and secondary syphilis are the most infectious and symptomatic stages. Periods of latency vary and may lead to increased morbidity and, potentially, mortality.

APPENDICES

A probable case of congenital syphilis is defined as "a condition affecting an infant whose mother had untreated or inadequately treated syphilis at delivery, regardless of signs in the infant, or an infant or child who has a reactive treponemal test for syphilis and any one of the following:

- Any evidence of congenital syphilis on physical examination;
- Any evidence of congenital syphilis on radiographs of long bones;
- A reactive cerebrospinal fluid (CSF) venereal disease research laboratory (VDRL);
- An elevated CSF cell count or protein (without other cause);
- A reactive fluorescent treponemal antibody absorbed - 19S-IgM antibody test; or
- Igm enzyme-linked immunosorbent assay" (CDC 1997).

A syphilitic stillbirth is defined as "a fetal death that occurs after a 20-week gestation or in which the fetus weighs >500g and the mother had untreated or inadequately treated syphilis at delivery" (CDC 1997).

Appendix B: Geocoding Methodology and Limitations

INEDSS - ADDRESS VALIDATION

On March 24, 2012, INEDSS Release 10.2 was deployed. This release included address validation within INEDSS and geocoded data. Before case information is submitted to the Illinois Department of Public Health (IDPH) for counting, addresses are verified to ensure the accuracy and standardization of the data. Addresses that are verified in INEDSS will be assigned latitude and longitude coordinates. For addresses not validated, INEDSS geocodes the data using the zip code centroid, followed by the city and then the country.

Twice a month, IDPH submits an updated morbidity file to CDPH via MOVEit File Transfer, a secured application for exchanging confidential files and data between servers and organizations. This file does not include the geocoded address field. Once CDPH receives the electronic file, it is prepared for submission to the City of Chicago GIS FTP server for validation and geocoding.

GEOCODING INEDSS MORBIDITY FILE

Before the INEDSS data file is submitted to the City of Chicago GIS FTP site, the street address is rounded (e.g. 8634 to 8600) in order to preserve confidentiality. A new data file is created containing only the rounded street address and a record identifier (state case number). This file is converted from Microsoft Excel to a common delimited (.csv) file and submitted to the City of Chicago GIS FTP server for processing.

The files submitted are assigned a name that does not associate it with a person, case, health condition or CDPH. Once the geographic identifiers (e.g., community area number, zipcode, ward and 2010 census tract) are selected, the file is submitted. After the geocoder has received the request, an email is sent notifying the user that the geocoding process has commenced. When the geocoding job is completed, the results (output) file is downloaded to a secure server that meets HIPPA security requirements. Lastly, the original (input) file that was submitted and the results (output) file are both deleted from the FTP folders.

Addresses that are not geocoded in the output file are cleaned using the Geocoder website by identifying the correct street components. All apartment components (e.g., FL, BSMT, Apt #1) are also removed from the address field. The file is resubmitted to the GIS FTP server for validation and geocoding. To increase the number of geocoded addresses, the match standard code can be changed from medium (default) to low to obtain nearest matches.

REASONS WHY ADDRESSES FAIL TO MATCH

- A. Addresses may be missing street segments or in the wrong format (AVE, ST., King Dr. instead of Dr. Martin Luther King Drive).
- B. Addresses may incorporate typographical errors that result in erroneous street names or local street names that are different than those officially recorded by the government.
- C. Addresses may end at jurisdictional boundaries.

APPENDICES

LIMITATIONS IN DETERMINING GEOGRAPHIC PATTERS IN RATES OF HEALTH-RELATED EVENTS

- Unable to determine if the geographical variation in the incidence rates across years is due to a true change in the progression of the disease or an artifact of the address validation process in INEDSS.
- Inflation of the rates due to increase in the proportion of exact or nearest matched addresses.

Appendix C: List of Acronyms

AI/AN = American Indian/Alaskan Native

AIDS = Acquired Immunodeficiency Syndrome

ART= Anti-Retroviral therapy

CDC = Centers for Disease Control and Prevention

CDPH = Chicago Department of Public Health

CHAT = Chicago Healthy Adolescents and Teens Program

CPS = Chicago Public Schools

eHARS = Enhanced HIV/AIDS Reporting System

EHI = Economic Hardship Index

EMSA = Eligible Metropolitan Statistical Area

FtM = Female to Male Transgender

HIV = Human Immunodeficiency Virus

HOPWA = Housing Opportunities for Persons with AIDS

IDPH = Illinois Department of Public Health

IDU = Injection Drug Use/Injection Drug User

INEDSS = Illinois National Electronic Disease Surveillance System

GIS = Geographic Information Systems

MtF = Male to Female Transgender

MSM = Men who have sex with men

MSM/IDU = Men with a history of injection drug use who have sex with men

NIR = No identified risk

NH = Non-Hispanic

PI = Pacific Islander

PID = Pelvic Inflammatory Disease

PLWH = People Living with HIV/AIDS

P&S Syphilis = Primary and Secondary Syphilis

STI = Sexually Transmitted Infection

APPENDICES

Appendix D: Technical Notes – Hardship Index

CHICAGO COMMUNITY AREA ECONOMIC HARDSHIP INDEX

The economic hardship index (EHI), developed by Richard P. Nathan and Charles F. Adams Jr. in 1975, is used to provide a complete, multidimensional measure of neighborhood socioeconomic conditions of inequality across the City of Chicago. The EHI is a composite of six indicators:

- Crowded housing (percentage occupied by housing units with more than one person per room);
- Poverty (percentage of persons living below the federal poverty level);
- Unemployment (percentage of persons over the age of 16 years who are unemployed);
- Education (percentage of persons over the age of 25 years without a high school education);
- Dependency (percentage of the population under 18 or over 64 years of age);
- Per capita income level.

The EHI score is a median of the six indicators that are standardized on a scale of 0 to 100, with a higher score representing a greater level of economic hardship or burden. The U.S. Census Bureau's American Community Survey estimates are used to calculate index values at the census tract levels. To calculate index values at the Chicago Community Area boundaries, the census tract data are aggregated using the Geographic Information Systems (GIS) software.
